The Effects of Macronutrients on Inducing Satiety via Peptide YY

By: Caroline E. Hubbard, Heidi A. Kluess, Leslie E. Neidert, Elise K. Mann

Several metabolic polypeptides are present in the saliva. These include peptide YY (PYY), which is a known substrate of the enzyme dipeptidyl-peptidase IV (DPP-IV). DPP-IV cleaves PYY into PYY3-36, a form that can bind to the Y2 receptor in the mouth that is involved in sending signals of satiety to the brain (Acosta et al., 2011; La Sala et al., 2013; Moran, 2009). Although it is suggested that satiety is mediated by a mechanism in the mouth, the physiological mechanism is not well understood. The purpose of this study was to investigate the effects of glucose and whey protein on salivary DPP-IV activity, salivary PYY levels, and feelings of satiety.

Twelve healthy college-age subjects participated in the study. During each visit, subjects either consumed whey protein (Optimum Nutrition, Aurora, IL, USA) or glucose (Sierra Mist, PepsiCo, Purchase, NY, USA). During each visit, satiety was measured via a visual analog questionnaire, and samples of saliva and blood were taken for biochemistry measurements (Chaput, Gilbert, Gregersen, Pedersen, & Sjödin, 2010). All measurements were collected pre-condition and thirty minutes post-condition. A fluorometric assay (Scharpé et al., 1988) was used to measure DPP-IV activity in the saliva and plasma. A PYY enzyme immunoassay (PYY3-36 human, Phoenix Pharmaceuticals, Inc., Burlingame, CA) was utilized to determine salivary PYY protein levels. The visual analog scale contained a series of five questions regarding perceived hunger and satiety, and subjects indicated their answers on a 100 mm line below each question. Satiety composite measures were calculated using a verified mathematical formula from previous literature (Chaput, Gilbert, Gregersen, Pedersen, & Sjödin, 2010).
We analyzed DPP-IV activity, PYY levels, and composite satiety scores. The mean saliva DPP-IV activity levels for the carbohydrate condition and the whey protein condition showed no significant change from pre to post condition (Fig. 1A). There was no significant change between pre and post condition with the plasma DPP-IV for both the carbohydrate and whey protein condition (all: 35.7±8.6U/L). The pre-whey protein condition PYY levels were significantly higher than the pre-carbohydrate condition PYY levels (*p < 0.05 different from Pre-CHO, Fig. 1B). This result can be attributed to natural variation, as the two conditions were counterbalanced. PYY levels did not significantly change from pre to post for either of the two conditions. In the whey protein condition, the satiety composite scores significantly decreased from pre to post (+: p < 0.05 different from pre whey; a: p < 0.05 different from post-CHO, Figure 1C). This decrease in composite satiety score indicated the subjects felt more sated after drinking the whey protein shake. There was no significant change in satiety measure seen for the carbohydrate condition.
